

# Magnifying lenses

It is a given fact that an operation to the thyroid or the parathyroid glands is “delicate”, due to human anatomy itself. More especially, when a malignant disease changes dangerously the normal relation between the organs, then **the precision in identifying and the protection of vital anatomic elements take on the highest importance.**

Dr Karvounis, depending on the gravity and the anatomical peculiarities of each case, uses a surgical lighting mirror that can optionally be connected to **surgical magnifying lenses (surgical loops).**

The High Definition Binocular Loops provides the surgeon with total image clarity in his surgical field. A system of multiple lenses and crystals, with magnification and focal distance at choice, at the same time reduces light reflection and offers the **ideal Depth & Breadth of Field.** The state of the art high resolution optics technology ensures an image with clarity of colour, without warping in the field and grants the Endocrine Surgeon **higher optical sharpness and resolution.**
